

Investigating Informal vs Formal in Jakarta

What you are attempting?

I want to understand how the expansion of formal public transportation in Jakarta relates to the distribution of informal food vendors over time. By comparing vendor data with the development of MRT, KRL, and TransJakarta, I want to identify which areas may be more vulnerable to changes or displacement as transportation infrastructure expands.

The Dataset

The main dataset is government data on street food vendors across Jakarta, organized by **year** and **administrative area**. I will use the year, **subdistrict**, and **number of vendors**, although there are gaps between some years. The second dataset will document **public transportation stations**, including their location, transit type, **opening year**, operation period, and, if available, passenger traffic.

Research

I will look at research on the relationship between **public transportation, informal economies, and economic development**. The MIT Gov/Lab research on Jakarta's informal transportation sector is relevant, as well as research on Transit-Oriented Development and economic activity. I will also use studies that have examined relationships between transit infrastructure and economic activity in other cities, such as New York, as methodological precedents.

What you are attempting?

My starting record will combine the annual food-vendor data with the timeline of public transportation development. For each sub district and year, I want to record the number of vendors, nearby or existing transit stations, transit type, and when stations became operational. Because some years are missing, I will need to identify where estimation is necessary.

Rule

For each subdistrict, I will compare changes in vendor concentration with changes in public transportation infrastructure. The rule will consider how many stations are present, when new stations open, and how close they are to areas with high vendor concentrations. If traffic data is available, I will also use it to measure the intensity of transit activity.

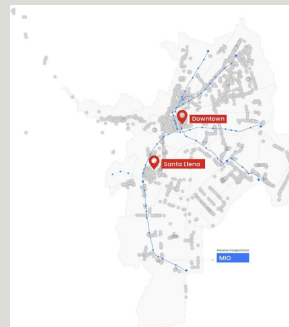

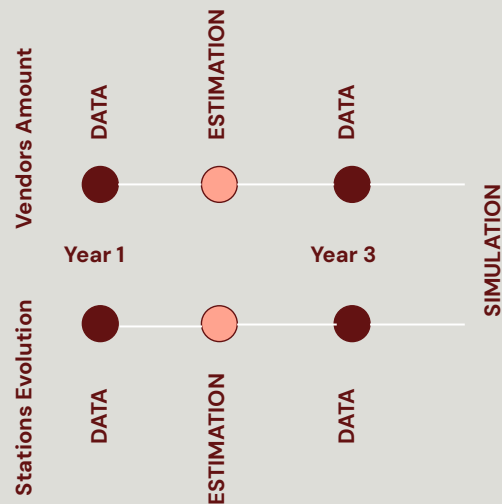

Run

The simulation will move forward year by year. First, I will analyze the historical data to see whether there is a relationship between transit expansion and changes in vendor concentration. I will then use those relationships to simulate future conditions and identify sub districts that may be more vulnerable to changes in the informal food economy.

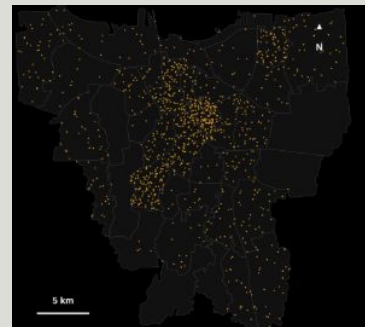

What we can't see

My starting record will combine the annual food-vendor data with the timeline of public transportation development. For each subdistrict and year, I want to record the number of vendors, nearby or existing transit stations, transit type, and when stations became operational. Because some years are missing, I will need to identify where estimation is necessary.
